What is the star made of at each radius?

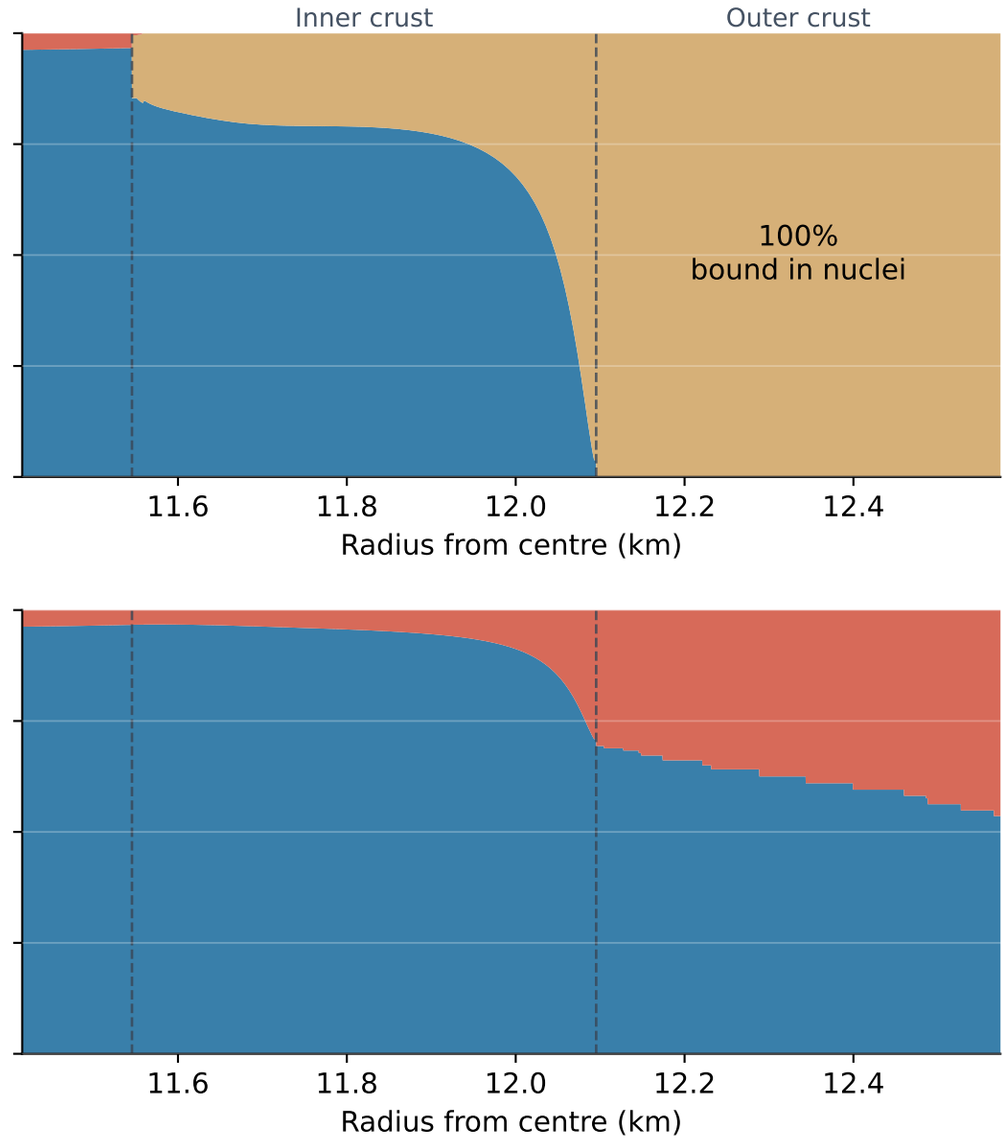

BSk24 | $M = 1.4\,M_\odot$ | $R = 12.57$ km • Percentages count baryons locally

Superfluid illustration: assume ALL unbound neutrons are paired. Lattice = baryons bound in nuclear clusters.

Whole star

Crust enlarged

Bound neutrons count as neutrons AND as part of the lattice. Electrons and muons carry no baryon number and are excluded from these percentages.

Pairing gaps, temperature and entrainment are not solved. BSk24 composition example; this is a separate model from the workspace's APR star.
